NOAA TECHNICAL MEMORANDA

National Weather Service, Tropical Prediction Center Subseries

The National Weather Service Tropical Prediction Center (TPC) subseries provides an informal medium for the documentation and quick dissemination of results not appropriate, or not yet ready, for formal publication. The series is used to report on work in progress, to describe technical procedures and practices, or to relate progress to a limited audience and hence will not be widely distributed.

Technical Memoranda originated at the Tropical Prediction Center prior to the establishment of this series are listed below. They were published as ESSA Technical Memoranda, WBTM or NOAA Technical Memoranda, NWS SR or NWS NHC.

Beginning with WBTM SR 38, the papers are available from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA, 22151 (Phone: 703-487-4650). Order by accession number shown in parenthesis at end of each entry.

ESSA Technical Memoranda

SRTM 28 The Weather Distribution with Upper Tropospheric Cold Lows in the Tropics. Neil L. Frank - September 1966

WBTM SR 38 Florida Hurricanes. Gordon E. Dunn and Staff NHC - November 1967 (PB 182 220)

WBTM SR 42 Memorable Hurricanes of the United States Since 1873. Arnold L. Sugg and Robert L. Carrodus - January 1969 (PB 182 228)

WBTM SR 44 Climatology of Atlantic Tropical Cyclones by Two and One-Half Degree Latitude-Longitude Boxes. John R. Hope and Charles J. Neumann - February 1969 (PB 183 308)

WBTM SR 45 On the Maximum Sustained Winds Occurring in Atlantic Hurricanes. Charles Holliday - May 1969 (PB 184 609)

WBTM SR 46 Hemispheric Circulation and Anomaly Patterns Observed When Tropical Storms Reach Hurricane Intensity. Paul J. Hebert, NHC, and Banner I. Miller, NHRL - May 1969 (PB 184 610)

WBTM SR 47 Disturbances in the Tropical and Equatorial Atlantic. R. H. Simpson - June 1969 (PB 184 740)

WBTM SR 49 A Mean Storm Surge Profile. Arnold L. Sugg - December 1969 (PB 188 422)

WBTM SR 50 A Reassessment of the Hurricane Prediction Problem. Robert H. Simpson - February 1970 (PB 189 846)

WBTM SR 51 The Satellite Applications Section of the National Hurricane Center. R. H. Simpson and D. C. Gaby - September 1970 (COM 71 00005)

PREFACE

This version of the Deadliest, Costliest, and Most Intense United States Hurricanes of This Century is an update through the 1995 hurricane season of Hebert, Jarrell and Mayfield (1995). This update is largely to include the 1995 season and adds information on hurricanes affecting Puerto Rico and the U. S. Virgin Islands.

Information for Hawaii, Puerto Rico and the Virgin Islands, given in Table 14, was provided by Hans Rosendal and Raphael Mojica of the Weather Service Forecast Offices in Honolulu and San Juan, respectively.

During 1995 the former National Meteorological Center, which included the National Hurricane Center, was re-organized into the National Centers for Environmental Prediction (NCEP). Under NCEP, the National Hurricane Center became the Tropical Prediction Center (TPC) to more accurately reflect the majority of its operational products being non-hurricane related, routine tropical forecasts. The name "National Hurricane Center" was retained to apply to the hurricane operations desk at TPC. We will follow the convention of using "NHC" to refer to the previous National Hurricane Center, "TPC" to refer to the current center and "TPC/NHC" to refer to the hurricane operations desk of TPC.

THE DEADLIEST, COSTLIEST, AND MOST INTENSE UNITED STATES HURRICANES OF THIS CENTURY (AND OTHER FREQUENTLY REQUESTED HURRICANE FACTS)

by
Paul J. Hebert, NEXRAD Weather Service Forecast Office
Jerry D. Jarrell & Max Mayfield, Tropical Prediction Center
National Weather Service
Miami, Florida.

ABSTRACT

Lists of the thirty United States deadliest and costliest land falling hurricanes during this century have been compiled from all data sources available at the Tropical Prediction Center (TPC). Damages are given both before and after adjustment for inflation. In addition, all major[1] hurricanes which have made landfall in the United States during this century are listed. Some additional statistics on United States hurricanes of this and previous centuries and tropical cyclones in general are also presented.

1. INTRODUCTION

Numerous requests are received at the Tropical Prediction Center for statistical information on deaths, damages, and severity of hurricanes which have affected the United States. Various reference materials give different estimates of these statistics so that decisions have to be constantly made as to which information should be given out by TPC as "official" from the National Hurricane Information Center (another function of TPC). Requests to other Weather Service offices posed the same dilemma. These lists are published in the hope of presenting a single source of the best currently available estimates of deaths, damages, and intensity of major U.S. hurricanes which have made landfall in this century. In some instances, data in these lists present revised estimates. Such estimates, for individual hurricanes, are based on more complete information received after earlier published values, including the previous versions of this technical memorandum. There are other frequently asked questions about hurricanes. What is the average number of hurricanes per year? What year(s) had the most and least hurricanes? What hurricane had the longest life? When did the earliest and latest hurricane occur? What was the most intense Atlantic hurricane? What was the largest number of hurricanes in existence on the same day? When was the last time a major hurricane or any hurricane hit a given community directly[2]? Answers to these and several other questions are provided in Section 3.

---

[1] A major hurricane is a category 3, 4, or 5 on the Saffir/Simpson Hurricane Scale (see Table 1), and is comparable to a Great Hurricane in other publications.

[2] A direct hit means experiencing the core of strong winds and high tides of a hurricane.

Table 1. Saffir/Simpson Hurricane Scale Ranges.

Scale Number (Category)	Central Pressure (Millibars)	Central Pressure (Inches)	Winds (Mph)	Surge (Feet)	Damage
1	>979	>28.91	74-95	4 to 5	Minimal
2	965-979	28.50-28.91	96-110	6 to 8	Moderate
3	945-964	27.91-28.47	111-130	9 to 12	Extensive
4	920-944	27.17-27.88	131-155	13 to 18	Extreme
5	< 920	< 27.17	> 155	> 18	Catastrophic

2. CRITERIA

The statistics in most of the tables and figures in this publication depend directly on the criteria used in preparing another study, Hurricane Experience Levels of Coastal County Populations-Texas to Maine (Jarrell, Hebert, and Mayfield, 1992). The primary purpose of that study was to demonstrate, county by county, the low hurricane experience level of a large majority of the population. Statistics show that the largest loss of life and, for the most part, property occur in locations experiencing the core of a category 3 or higher hurricane. Unless a given population has experienced this core, or direct hit, with its very strong winds and high tides, it would defeat the primary purpose of the study on hurricane experience levels to so categorize it.

Although the Saffir/Simpson category is defined by pressure, wind, and storm surge, in practice it is the maximum wind speed that determines the category. Operationally, the central pressure is used to make a first estimate of the wind. Thereafter, available surface wind reports and aircraft reconnaissance flight level winds (which must be reduced to the surface) are used to anchor the wind estimate. In post-analysis, the central pressure ranges of hurricanes on the Saffir/Simpson scale will usually agree fairly well with the wind ranges in that category.

On the other hand, the surge is strongly dependent on the slope of the continental shelf (shoaling factor). This can change the height of the surge by a factor of two for a given central pressure and/or maximum wind.

Heavy rainfall associated with a hurricane is not one of the criteria for categorizing it.

The subjective determination of which category number to assign to a hurricane, as well as its direct or indirect effect, is made on a county by county basis with the intent of the study on hurricane experience levels foremost in mind.

As with the assignment of scale numbers, a certain amount of subjectivity was inescapable at times in determining which counties received direct or indirect hits during the various hurricane situations. However, certain arbitrary guidelines for these classifications as used in Hurricane Experience Levels, etc., are indicated below:

> Direct Hit - When the innermost core region or "eye" moved over a county, it was counted as a direct hit. Using "R" as the radius of maximum winds in a hurricane (the distance in miles from the storm's center to the circle of maximum winds around the center), all or parts of counties falling within approximately 2R to the right and R to the left of a storm's landfall point were considered to have received a direct hit. (This assumes an observer at sea looking toward the shore. If there was no landfall, the closest point of approach was used in place of the landfall point). On the average, this direct hit zone extended about 50 miles along the coastline ($R \approx 15$ miles). Of course, some hurricanes were smaller than this and some, particularly at higher latitudes, were much larger. Cases were judged individually, and many borderline situations had to be resolved.

Indirect Hit - These were based primarily on a hurricane's strength and size, and on the configuration of the individual county coastline. Here again, much subjectivity was necessary in many cases which were complicated by storm paths and geography. Generally, those areas on either side of the direct hit zone which received at least wind gusts of hurricane force and/or tides of 4 to 5 feet or more above normal were considered to have had an indirect hit.

It is realized that the effect of an indirect hit by a large category 4 hurricane might be greater than that of a direct hit by a small category 1 affecting the same county. However, trying to account for these differences would hopelessly complicate the use of this system.

A study by Simpson and Lawrence (1971) gives climatological probabilities of the total number of storms and hurricanes to affect the U.S. coastline by fifty-mile wide coastal segments, as well as only hurricanes, and major (or great) hurricanes. While this 50 miles approximates that of the "core" used for direct hits, there are some differences. In the Simpson and Lawrence study, a storm/hurricane/great hurricane was counted in the segment where it crossed the coast plus the next segment to the right. As indicated earlier, the "core" used in Jarrell, Hebert, and Mayfield (1992) can be smaller or larger than 50 miles, and could also affect one of the segments in Simpson and Lawrence to the left of a coastline crossing which that study would not count.

The foregoing two studies and their associated criteria are climatological with their primary purpose being for use in assessing risk based on past experience. On the other hand, the National Weather Service's Hurricane Probability Program has as its purpose the assessment of risk based on a present hurricane threat to the United States coastline. It does this by arbitrarily defining a "strike" as the center of a hurricane moving through a zone within approximately 50 nautical miles to the right or 75 nautical miles to the left of the site of interest (Sheets, 1984). The asymmetry is to allow for the strongest winds in a hurricane frequently being further to the right of the center than the left - a consideration reflected also in the earlier studies discussed. This 125 nautical mile diameter circle approximates the region of hurricane force winds for a "typical" hurricane. It will usually be larger than the "core", and is fixed, like the segments in Simpson and Lawrence. HURRICANE STRIKE PROBABILITIES HAVE NO RELATION TO HURRICANE INTENSITY. Users of these probabilities must take the intensity and expected arrival time of tropical storm and hurricane force winds into account when assessing risk. The reader is urged to refer to The National Weather Service Hurricane Probability Program (Sheets, 1984) for a more thorough explanation of forecast probabilities.

Statistics on total storm/hurricane activity in the North Atlantic Ocean (which includes the Gulf of Mexico and the Caribbean Sea) can be found in Neumann, et al. (1993). A detailed breakdown of hurricanes by category which have affected coastal counties of the Gulf of Mexico and North Atlantic Ocean both directly and indirectly can be found in Jarrell, Hebert, and Mayfield (1992), which has been updated where necessary for this technical memorandum. The best source of how a hurricane affected individual localities or states can be found in the annual articles on the hurricane season in the Monthly Weather Review (1995 for example) and Storm Data (1995 for example).

3. DISCUSSION
Part I

(1) **What have been the deadliest hurricanes of this century in the United States?** Table 2 lists the 30 deadliest hurricanes to strike the mainland U.S. in this century. Although technically incorrect, we have included 1900 in "this century". Three hurricanes prior to 1900, a tropical storm which affected southern California in 1939 and deadliest hurricanes affecting Puerto Rico and the Virgin Islands are listed as an addendum because of their large death tolls.

(2) **What have been the costliest hurricanes of this century in the United States?** Table 3 lists the 30 costliest hurricanes (including 4 tropical storms) to strike the mainland U.S. in this century. Figures are not adjusted for inflation. Table 3a re-orders some of these plus several other hurricanes (and 1 tropical storm) after adjusting to 1994 dollars[3]. Hawaiian, eastern Pacific, Puerto Rican and Virgin Island tropical cyclones are listed as addenda to Tables 3 and 3a.

(3) **What have been the most intense hurricanes to strike the United States during this century?** Table 4 lists the 63 major hurricanes which have struck the mainland U.S. during this century. Hurricanes are ordered by the lowest estimated central pressure and/or highest category to affect the United States at time of landfall. Hawaiian, Puerto Rican and Virgin Island hurricanes are listed as an addenda to Table 4. Many of the island hurricanes are close passes, as opposed to landfalls as defined above.

A look at the lists of deadliest and costliest hurricanes of this century reveals several striking facts: (1) The twelve deadliest hurricanes were all the equivalent of a category 4 or higher, if the excessive forward speed is considered as raising the category of a hurricane by one. (2) Large death totals were primarily a result of the 15 to 20 feet or more rise of the ocean (storm surge) associated with many of these major hurricanes. All but five of the thirty deadliest hurricanes were major hurricanes. Three of these five were the inland flood-producing hurricanes Agnes and Diane and Tropical Storm Alberto. (3) A large portion of the damage in three of the thirteen costliest tropical cyclones (Table 3) resulted from inland flooding caused by torrential rainfall in mountainous areas. (4) Three-fifths of the deadliest hurricanes were the equivalent of a category four or higher, but only one-third of the costliest hurricanes (Table 3) met this criterion. (5) Only one of the deadliest hurricanes (plus one deadly tropical storm) have occurred during the past twenty five years in contrast to three-fifths of the costliest hurricanes (this drops to two-fifths after adjustment for inflation).

Addenda to tables 2, 3 and 4 include some noteworthy storms from pre-1900, the U.S. Pacific coast and the Hawaiian islands, as well as the U. S. Caribbean Islands. The rank is where they would fall if each alone were ranked within the main table.

Notes

* Moving more than 30 miles per hour.

& Highest category justified by winds.

\# Classified 4 because of estimated winds.

\+ Cape Fear, NC area only; was a category 2 at final landfall.

Table 4a. Direct hits by mainland United States Hurricanes (1900-1995)

Category	Direct Hits
5	2
4	15
3	46
2	36
1	57
TOTAL	156
MAJOR	63

Major hurricanes are categories 3,4 & 5.

Table 4a summarizes the direct hits on the U. S. mainland this century. The implication of table 4a is that during the period 1900-1995, an average of 2 major hurricanes every 3 years made landfall somewhere along the U.S. Gulf or Atlantic coast. (All categories combined average about 5 hurricanes every 3 years for the same period.)

One of the greatest concerns of the National Weather Service's (NWS) hurricane preparedness officials is that the statistics in tables 2-4 will mislead people into thinking that no more large loss of life will occur in a hurricane because of our advanced technology. Dr. Robert Burpee, spokesman for the NWS hurricane warning service and Director of TPC, as well as former NHC Directors, Dr. Robert Sheets and Dr. Neil Frank, have repeatedly emphasized the great danger of a catastrophic loss of life in a future hurricane if proper preparedness plans for vulnerable areas are not formulated and maintained.

The study by Jarrell, Hebert and Mayfield (1992), using 1990 census data, showed that 85% of U.S. coastal residents from Texas to Maine had never experienced a direct hit by a major hurricane. Many of those 45 million residents had moved to coastal sections during the past twenty-five years. Even the landfalls of Andrew, Hugo and Opal have not lessened an ever growing concern brought by the continued increase in coastal populations.

Table 5 which lists hurricanes by decades in this century shows that during the twenty year period 1960-1979 both the number and intensity of landfalling U.S. hurricanes decreased sharply! Based on 1900-1959 statistics, the expected number of hurricanes and major hurricanes during the period 1960-1979 was 36 and 15, respectively. In fact, only 27 or 75% of the expected number of hurricanes struck the U.S. with only 10 major hurricanes or 67% of that expected number. The decade of the eighties showed little change to this trend. Even the decade of the nineties, to date, shows below average landfall frequencies. If the near record 1995 pace of storm frequencies continues, a reversal in the recent trend may be upon us.

On the average a category 4 or greater hurricane strikes the U.S. once every 6 years. Even with two category 4 hurricanes in three years, Hugo in 1989 and Andrew in 1992, these are the only category 4 hurricanes since 1969. Fewer hurricanes do not necessarily mean a lesser threat of disaster, however. The 1919 hurricane which is both the third deadliest and fourth most intense of this century to strike the U.S. occurred in a year which had a total of only three storms/hurricanes. Records for the most intense U.S. hurricane in 1935 and the costliest, Andrew in 1992, occurred in years which had only six tropical storms or hurricanes.

The conclusions are obvious. A large death toll in a U.S. hurricane is still possible. The decreased death totals in recent years may be as much a result of lack of major hurricanes striking the most vulnerable areas as they are of any fail-proof forecasting, warning, and observing systems. Continued coastal growth and inflation will almost certainly result in every future major landfalling hurricane (and even weaker hurricanes and tropical storms) replacing one of the current costliest hurricanes. If warnings are heeded and preparedness plans developed, the death toll can be reduced, but, in the absence of a change of attitude or laws restricting building near the ocean, large property losses are inevitable.

Table 5. Number of hurricanes by category to strike the mainland U.S. each decade. (Updated from Hebert et al. 1995)

	Category					ALL	Major
DECADE	1	2	3	4	5	1,2,3,4,5	3,4,5
1900-1909	5	5	4	2	0	16	6
1910-1919	8	3	5	3	0	19	8
1920-1929	6	4	3	2	0	15	5
1930-1939	4	5	6	1	1	17	8
1940-1949	7	8	7	1	0	23	8
1950-1959	8	1	7	2	0	18	9
1960-1969	4	5	3	2	1	15	6
1970-1979	6	2	4	0	0	12	4
1980-1989	9	1	5	1	0	16	6
1990-1995	0	2	2	1	0	5	3
1900-1995	57	36	46	15	2	156	63

Note: Only the highest category to affect the U.S. has been used

THIS PAGE LEFT BLANK INTENTIONALLY

In addition to information about U.S. hurricanes, this section also includes statistics on total tropical storm and hurricane activity.

(1) **What is the average number of hurricanes per year?** Table 6 gives the average number of tropical cyclones which reached storm strength and hurricane strength for various time periods. A total of ten tropical cyclones reaching storm strength with five or six of these becoming hurricanes appears to be the best averages to use based on the past 10 to 50 year time periods.

Table 6. Average number of tropical cyclones which reached storm and hurricane strength for various periods. Updated from Neumann, et al. (1993).

PERIOD	Number of years	Average number of Tropical Cyclones	Average number of Hurricanes
1886 - 1995	110	8.5	5.0
1946 - 1995	50	9.7	5.7
1956 - 1995	40	9.6	5.5
1966 - 1995	30	9.9	5.5
1976 - 1995	20	9.7	5.4
1981 - 1995	15	9.7	5.1
1986 - 1995	10	9.9	5.3

Includes subtropical storms after 1967

(2) **What year(s) have had the most and least hurricanes?** Table 7 shows the years of maximum and minimum tropical cyclone and hurricane activity for the entire Atlantic Ocean. The only years when a hurricane failed to strike the U.S. coast were 1902, 1905, 1907, 1914, 1922, 1927, 1930, 1931, 1937, 1951, 1958, 1962, 1973, 1978, 1981, 1982, 1990 and 1994. Note that only twice has the U.S. gone as long as two years without a hurricane. The most hurricanes to strike the U.S. in one year were six in 1916 and 1985. There were five in 1933, and four in 1906, 1909, and 1964. Three hurricanes have struck the U.S. in one year a total of fifteen times. Ten of these fifteen times occurred during the sixteen years from 1944 to 1959! A chronological list of all hurricanes to strike the U.S. during this century through 1991 including month, category by states affected, and minimum sea level pressure at landfall can be found in Jarrell, Hebert and Mayfield (1992).

Table 7. Years of maximum and minimum tropical cyclone and hurricane activity in the North Atlantic, Caribbean, and Gulf of Mexico 1871-1995 (updated from Neumann, et al., 1993)

MAXIMUM ACTIVITY

TROPICAL CYCLONES[1]		HURRICANES[2]	
Number	Years	Number	Years
21	1933	12	1969
19	1995	11	1916,1950,1995
18	1969	10	1887,1893,1933
17	1887	9	1955,1980
16	1936		

MINIMUM ACTIVITY

TROPICAL CYCLONES[1]		HURRICANES[2]	
Number	Years	Number	Years
1	1890,1914	0	1907,1914
2	1925,1930	1	1890,1905,1919, 1925
		2	1895,1897,1904 1917,1922,1930, 1931,1982

Notes
1 Includes subtropical storms after 1967.
2 Distinction of hurricanes recorded only after 1885.

(3) **When did the earliest and latest hurricane occur?** The hurricane season is defined as June 1 through November 30. An early hurricane can be defined as occurring in the three months prior to the start of the season, and a late hurricane can be defined as occurring in the three months after the season. With these criteria the earliest observed hurricane in the Atlantic was on March 7, 1908, while the latest observed hurricane was on December 31, 1954, the second "Alice" of that year which persisted as a hurricane until January 5, 1955. The earliest hurricane to strike the U.S. in this century was Alma which struck northwest Florida on June 9, 1966. The latest hurricane to strike the U.S. was late on November 30, 1925 near Tampa, Florida.

(4) **What were the longest-lived and shortest-lived hurricanes?** Ginger in 1971 holds the record for both the most number of days as a hurricane (20) and tropical cyclone (28). There have been many tropical cyclones which attained hurricane intensity for periods of 12 hours or less.

(5) **What were the strongest and weakest Atlantic hurricanes? To strike the United States?** In terms of central pressure (and probably winds), the strongest observed hurricane in the Atlantic basin was Gilbert in 1988 with a pressure of 888 millibars while located in the northwest Caribbean. The 1935 Labor Day hurricane in the Florida Keys with a pressure of 892 millibars was the strongest hurricane to strike the U.S. Numerous hurricanes have reached only the minimum wind speed near 74 miles per hour and struck the U.S.

(6) **How many hurricanes have there been in each month?** Table 8 adapted from Neumann, et al. (1993) shows the total and average number of tropical cyclones and those which became hurricanes by months for the period 1886-1995. In addition, the monthly total and average number of hurricanes to strike the U.S. in this century (updated from Hebert, Jarrell and Mayfield, 1995) are given.

Table 8. Tropical storms and hurricanes in the Atlantic, Caribbean and Gulf of Mexico by month of origin, 1886-1995 (updated from Neumann et al. 1993), and for hurricanes striking the U.S. mainland (updated from Hebert, et al. 1995).

[1] Includes subtropical storms after 1967. See Neumann, et al. (1993) for details.
[2] For 1900-1995, (updated from Hebert, Jarrell and Mayfield, 1995)
* Less than 0.05.

(7) **What was the largest number of hurricanes in existence in the Atlantic Ocean at the same time?** According to information on the current version of the master data file of Neumann, et al (1993), there have never been four hurricanes in existence in the North Atlantic at the same time in this century. On August 22, 1893 four hurricanes co-existed, one of them being the hurricane which killed an estimated 2,000 people in Georgia-South Carolina several days later. On September 11, 1961 three hurricanes and possibly a fourth existed. The only other years in this century with three hurricanes on the map at the same time were 1950 and 1967. In 1971 from September 10 to 12, there were five tropical cyclones in existence at once; however while four of these ultimately achieved hurricane intensity, never more than two were hurricanes at any one time.

(8) **How many direct hits by hurricanes of various categories have affected each state?** Table 9, updated from Hebert, Jarrell and Mayfield, (1995), shows the number of hurricanes (direct hits) affecting the U.S. and individual states. The table shows that on the average close to three hurricanes every two years (1.5 per year) strike the U.S., while two major hurricanes cross the U.S. coast somewhere every three years (0.67 per year). Other noteworthy facts, updated from Hebert, Jarrell and Mayfield, (1995), are: 1.) Thirty-seven percent of all U.S. hurricanes hit Florida; 2.) Seventy-one percent of category 4 or higher hurricanes have hit either Florida or Texas; 3.) Approximately half the hurricanes to strike along the middle Gulf coast, southern Florida, New York and southern New England are major ones.

Table 9. Hurricane direct hits on the mainland U.S. coastline and for individual states 1900-1995 by Saffir/Simpson category (updated from Hebert, et al. 1995).

Notes:

* Indicates all hurricanes in this group were moving faster than 30 mph. State totals will not equal U.S. totals, and Texas or Florida totals will not necessarily equal sum of sectional totals.

(9) **When are the major hurricanes likely to strike given areas?** Table 10 shows the incidence of major hurricanes by months for the mainland U.S. and individual states. For the United States as a whole, September has had more major hurricanes than all other months combined. However, four of the most devastating hurricanes did not occur in September--ANDREW (August 1992), CAMILLE (August 1969), AUDREY (June 1957), and HAZEL (October 1954). Only in Texas and Louisiana are major hurricanes in August and September almost an equal threat. Most major October hurricanes occur in southern Florida.

Table 10. Incidence of major hurricane direct hits on the mainland U.S. and individual states, 1900-1995, by Saffir/Simpson category. (Updated from Hebert, et al. 1995)

Note: State totals do not equal U.S. totals and Texas or Florida totals do not necessarily equal the sum of sectional entries.

(10) **How long has it been since a major hurricane directly hit a given community? Any hurricane? Indirectly?** Table 11 summarizes the occurrence of the last major hurricane or of any hurricane to directly hit the more populated coastal communities from Brownsville, Texas to Eastport, Maine. In addition, if a hurricane indirectly affected a community after the last direct hit, it is listed in the last column of the table. In order to obtain the same type of information listed in Table 11 for the remaining coastal communities, the reader is referred to Jarrell, Hebert and Mayfield (1992).

There are many illustrative examples of the uncertainty of when a hurricane might strike a given locality. Pensacola, Florida, in 1995 experienced a direct hit by hurricanes Erin and an indirect hit from major hurricane Opal within two months after a period of nearly 70 years without a direct hit. Miami, which expects a major hurricane every 25 years, on average, was struck by a major hurricane in 1992 for the first time since 1950. Tampa, hasn't experienced a major hurricane for 75 years. Many locations along the Gulf and Atlantic coasts have never experienced a major hurricane in this century (see Table 11).

(11) **What is the total United States damage (before and after adjustment for inflation) and death toll for each year of this century?** Table 12 summarizes this information. Tables 12a ranks the years by deaths, by unadjusted damage and by adjusted damage. In most years the death and damage totals are the result of a single, major hurricane. Gentry (1966) gives damages adjusted to 1957-59 costs as a base for the period 1915-1965. For the most part, death and damage totals for the period 1915-1965 were taken from Gentry's paper, and for the remaining years from the Monthly Weather Review. Adjusted damages were calculated to 1994 dollars by the same factors as used in Table 3a.

Table 11. Last direct or indirect hit by any or a major hurricane at certain populated coastal communities. Category in parenthesis (Updated from Jarrell, Hebert and Mayfield, 1992)

+ May actually have been as high as 10,000 to 12,000.

1 Adjusted to 1994 dollars based on U.S. Department of Commerce Implicit Price Deflator for Construction. 1995 adjusted downward.

2 Considered too high in 1915 reference.

3 Using 1915 cost adjustment - none available prior to 1915.

s Figures do not agree with table 2 because these figures are for landfalling hurricanes and do not include non-coastal deaths at sea.

(12) **Are there hurricane cycles?** Figures 1 through 10 show the landfalling portion of the tracks of major hurricanes which have struck any portion of the United States during this century. The reader might note the tendency of the major hurricanes to cluster in certain areas during certain decades. Another interesting point is the general tendency for this clustering to occur in the latter half of individual decades in one area and in the first half of individual decades in another area. During the very active period of the thirties this clustering is not apparent.

A comparison of twenty-year periods beginning in 1900 indicates that the major hurricanes tended to be in the western Gulf Coast states at the beginning of the century, shifting to the eastern Gulf Coast states and Florida during the next twenty years, then to Florida and the Atlantic Coast states during the forties and fifties, and back to the western Gulf Coast states in the sixties and seventies. Do figures 9 and 10 indicate a shift to the eastern Gulf Coast states, Florida, and the Atlantic Coast states in the eighties and nineties?

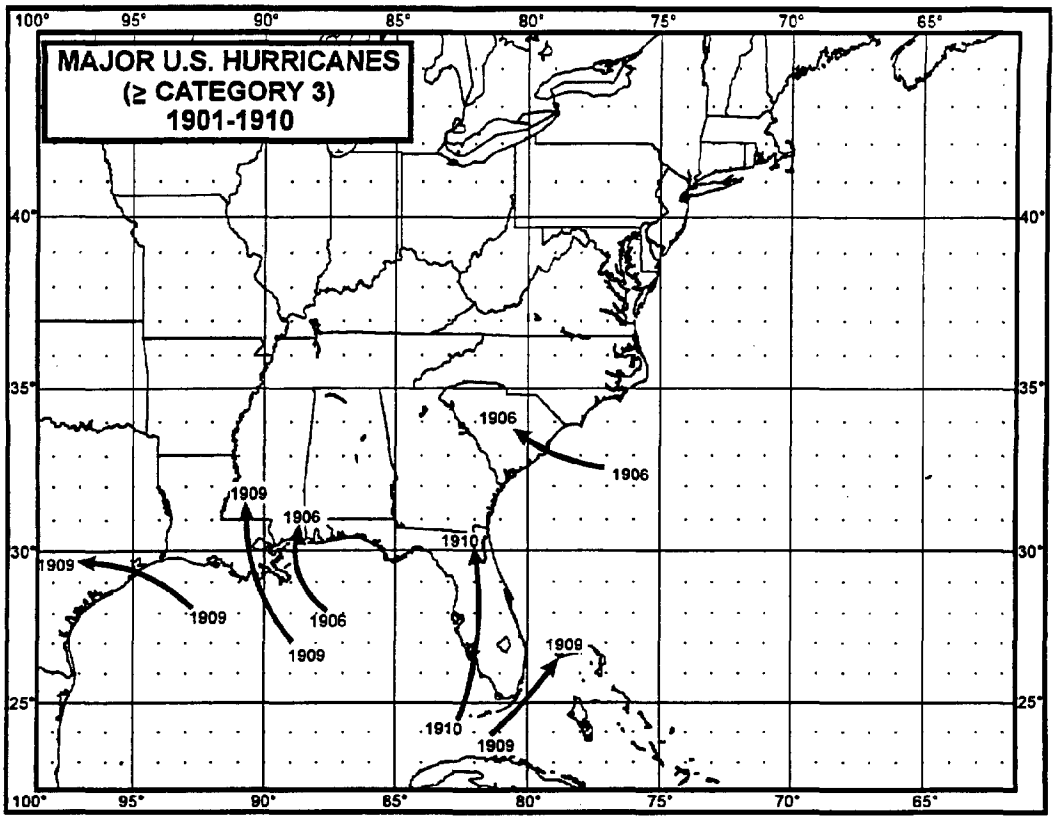

Figure 1. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1901-1910.

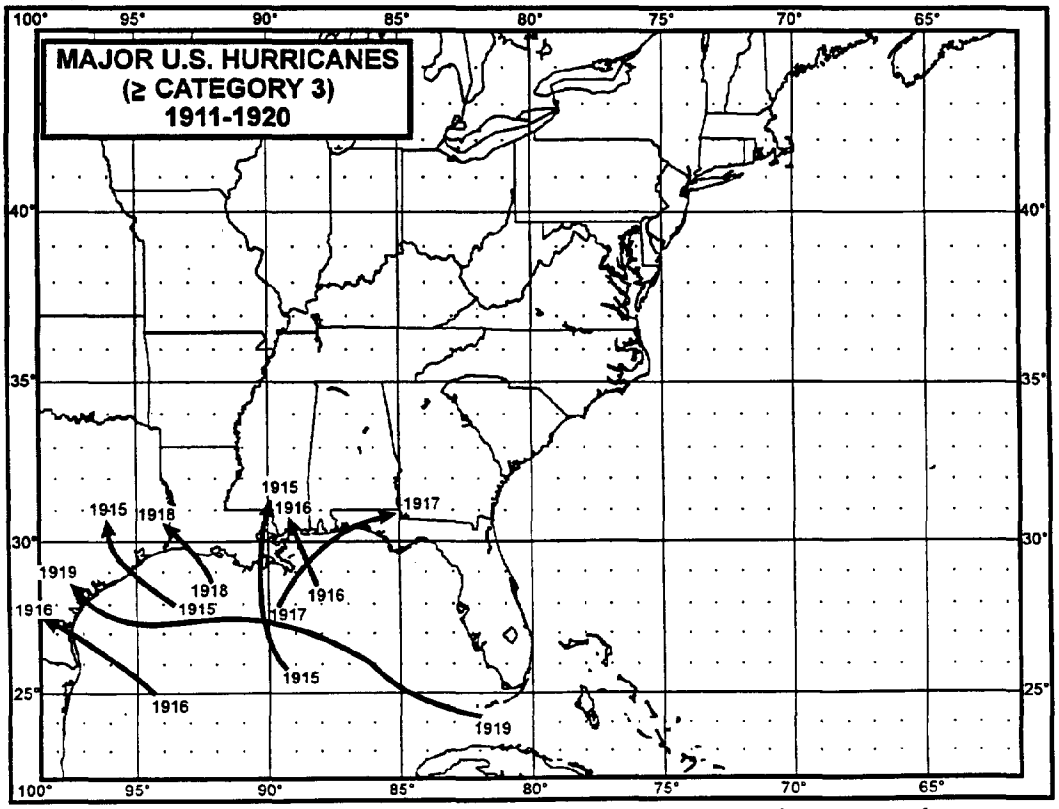

Figure 2. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1911-1920.

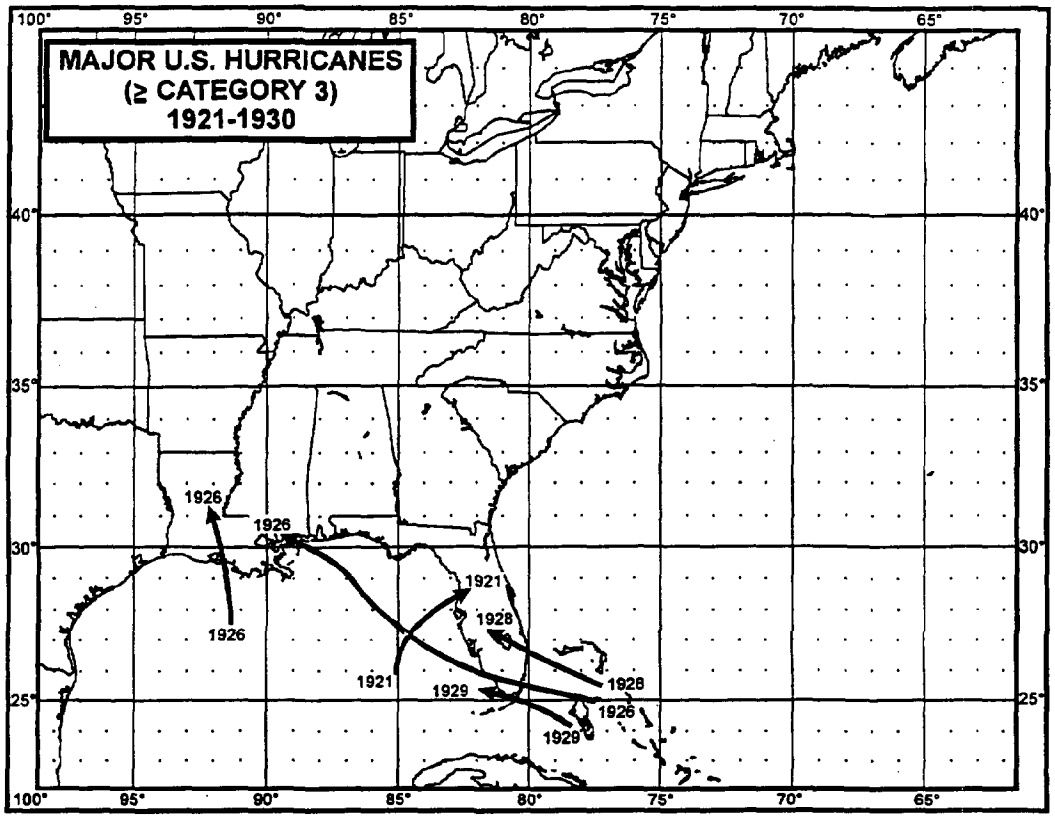

Figure 3. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1921-1930.

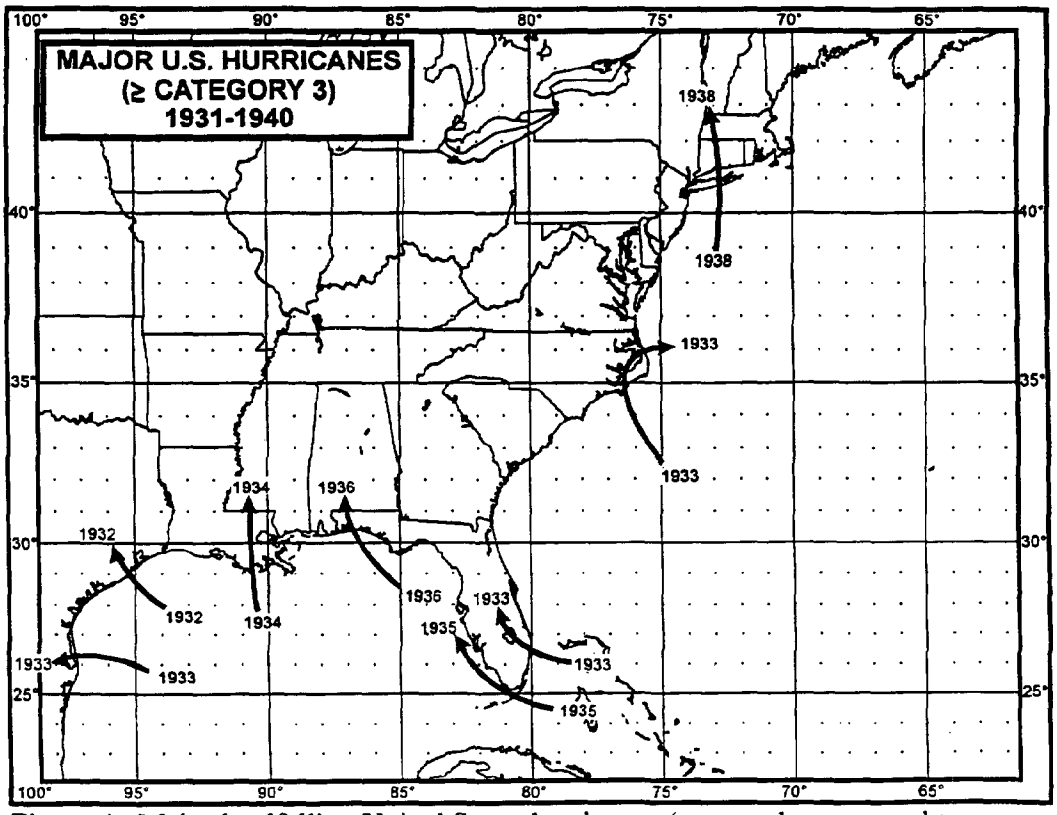

Figure 4. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1931-1940.

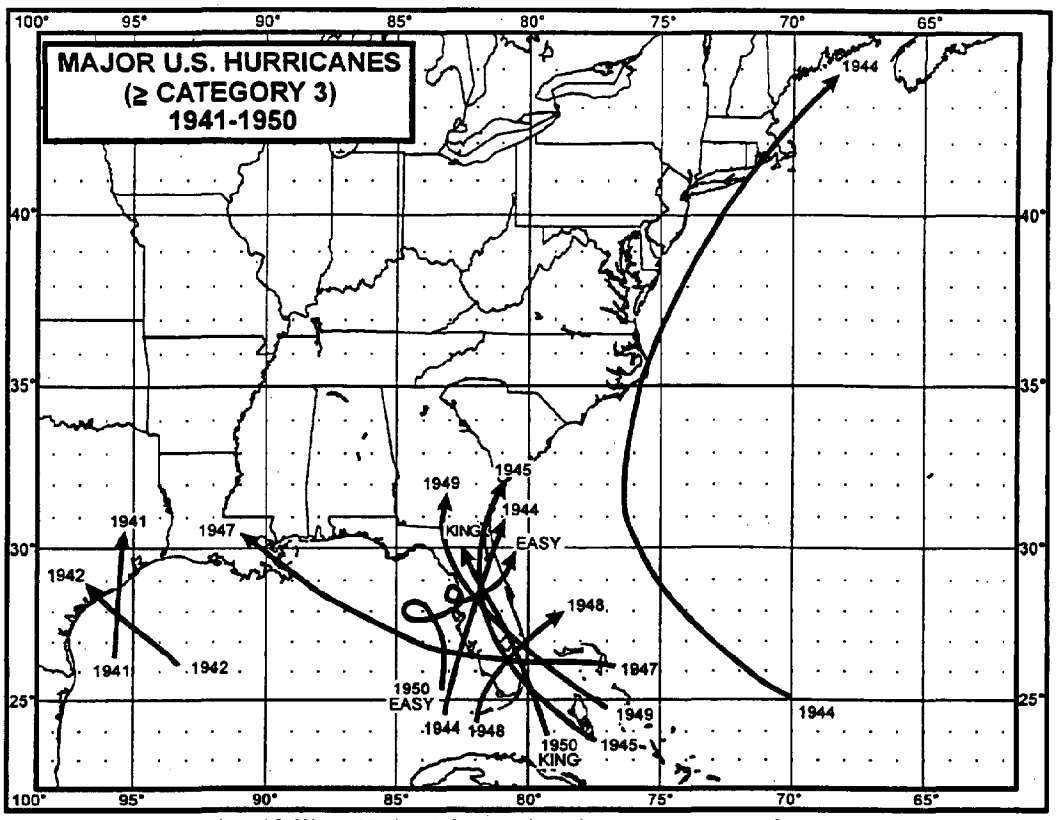

Figure 5. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1941-1950.

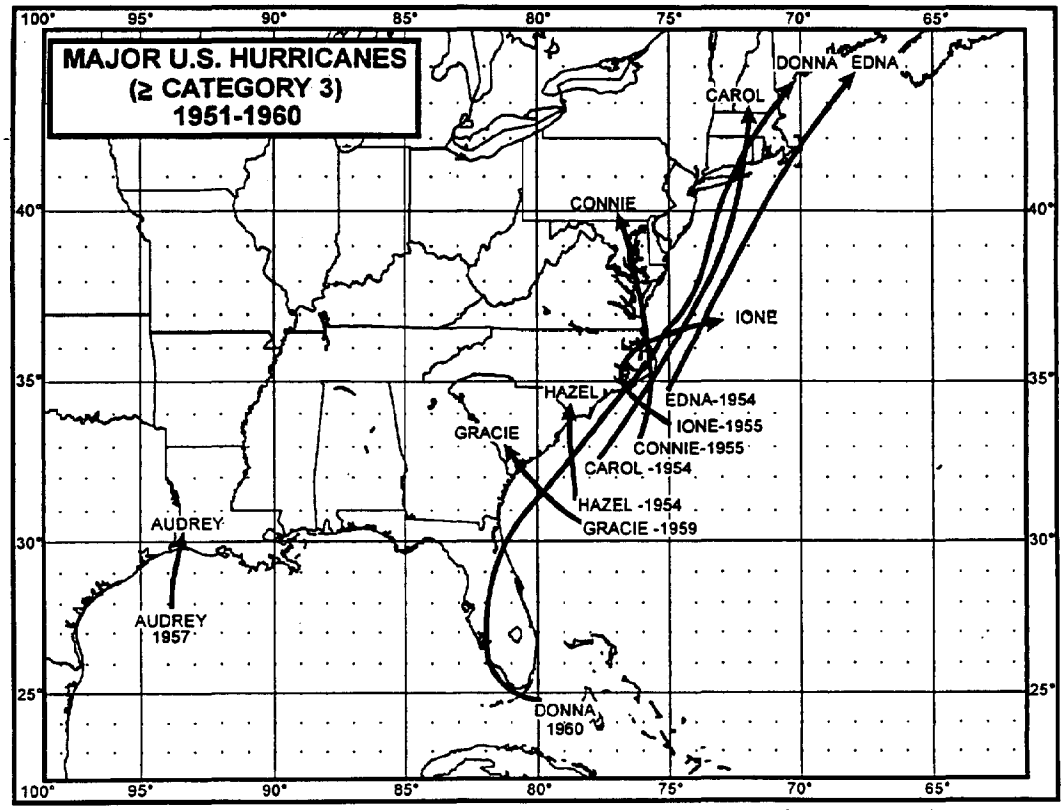

Figure 6. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1951-1960.

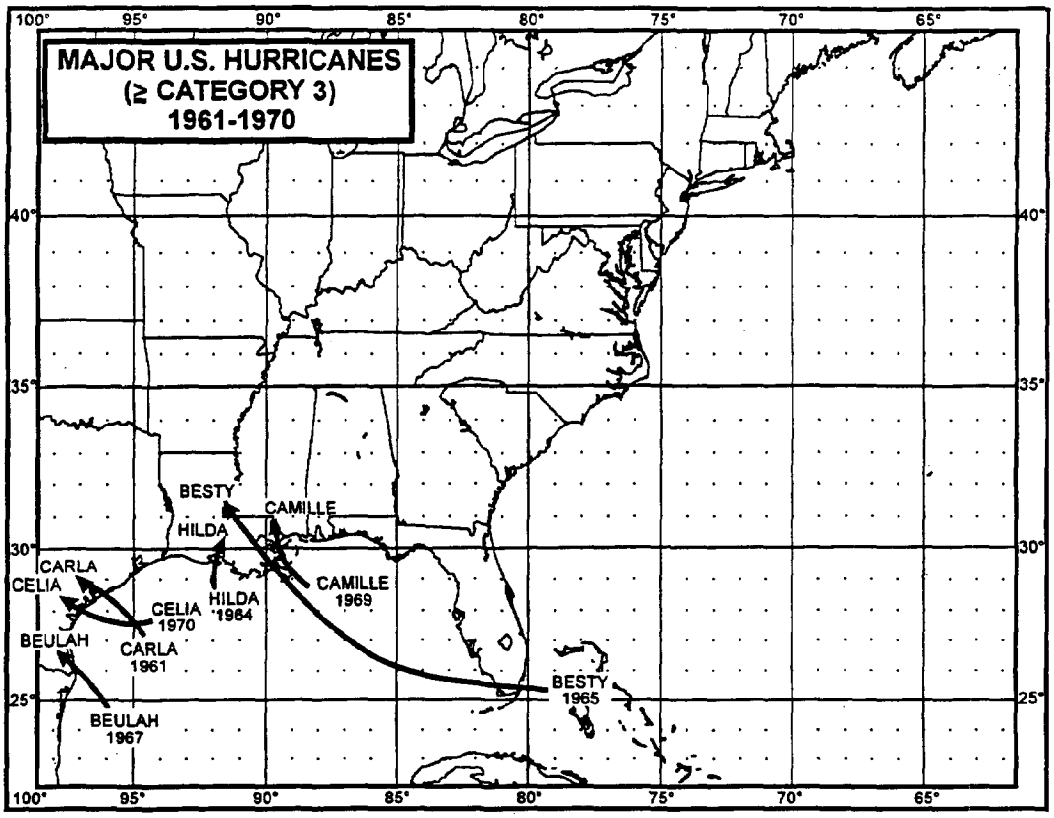

Figure 7. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1961-1970.

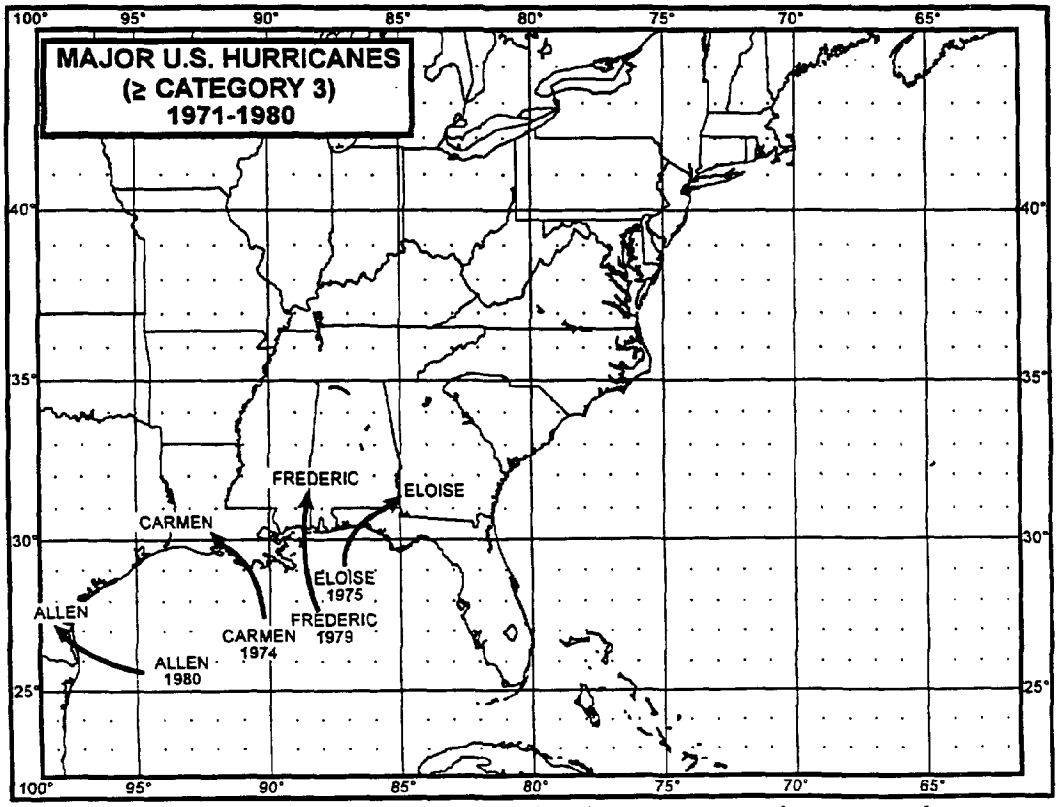

Figure 8. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1971-1980.

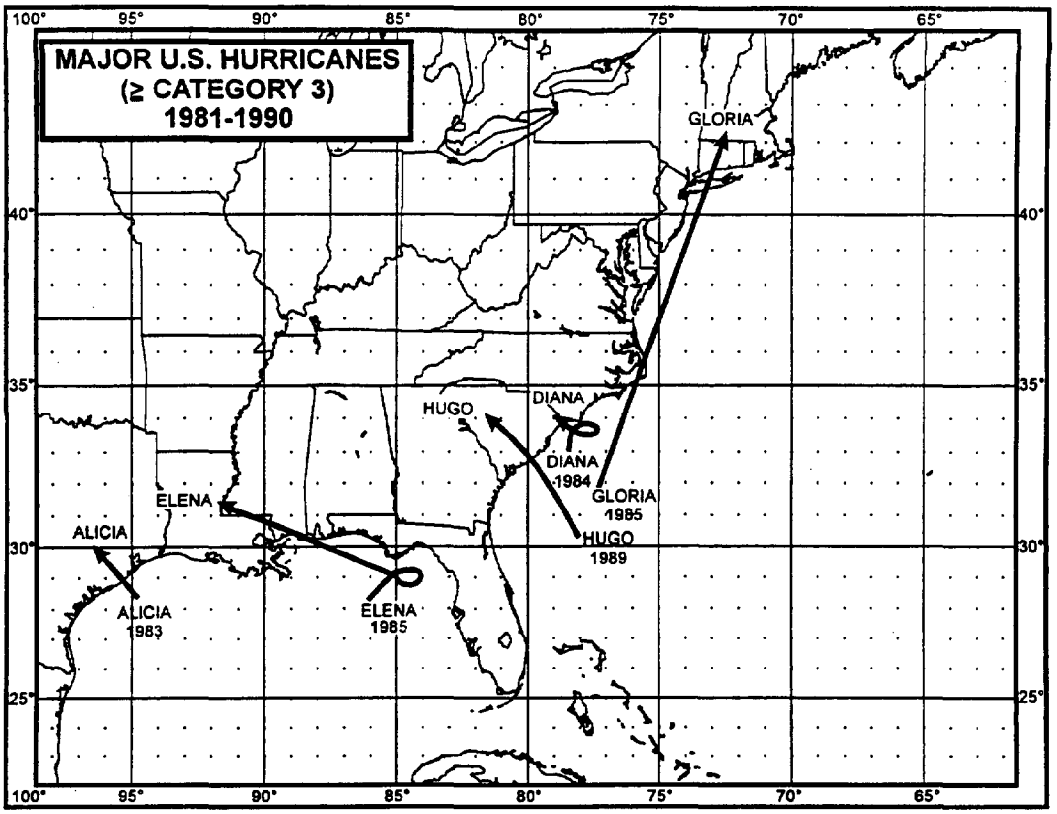

Figure 9. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1981-1990.

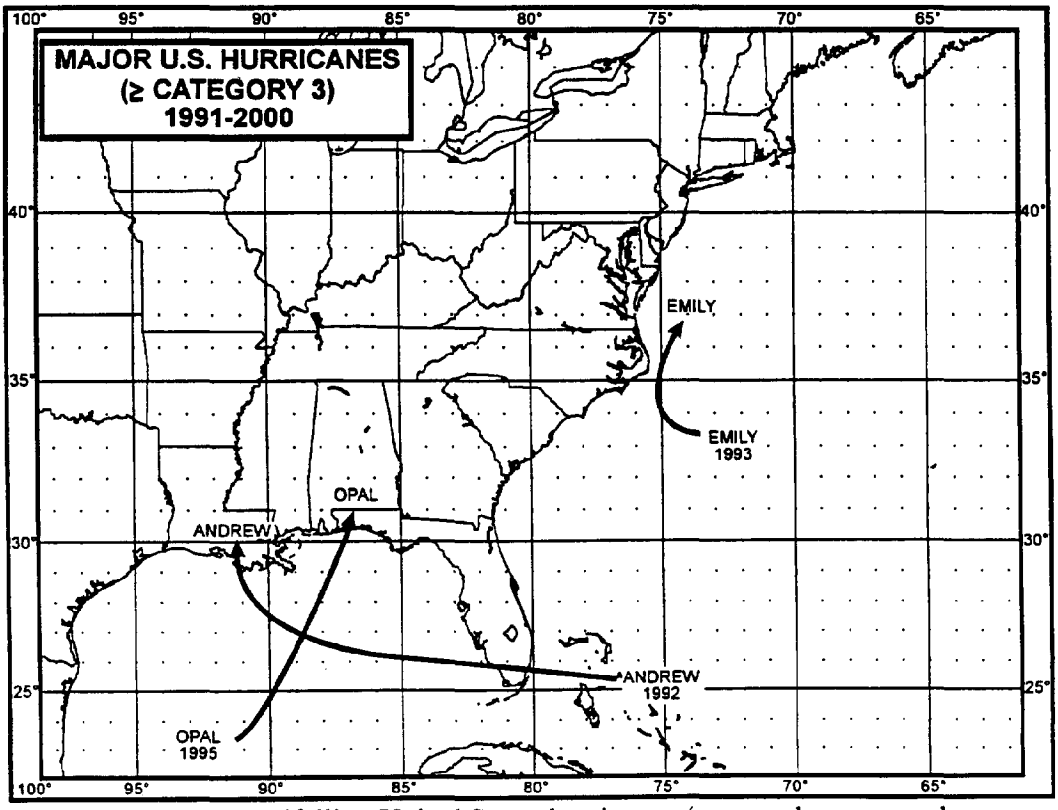

Figure 10. Major landfalling United States hurricanes (greater than or equal to a category 3) during the period 1991-2000.

(13) **Are there hurricane cycles evident in certain years regardless of category or geographical area?** Table 13 gives a tabulation of hurricanes of all categories to affect the U.S. by individual years within each decade.

Figures 1 through 10 certainly support the existence of a cyclical nature of major hurricanes affecting given regions. Table 13 is also suggestive of preferred periods. However, it is left to the reader to decide what weight should be given to these statistics.

Table 13. Major and all category landfalling hurricanes in the mainland United States by individual years.

[1] Effects continued into the following day. [2] Damage and Casualties from David and Frederic are combined.

Table 14 lists important hurricanes of Hawaii, Puerto Rico, and the U. S. Virgin Islands during the twentieth century. The Saffir/Simpson scale and the empirical Atlantic wind pressure relationship do not strictly apply in the Hawaiian area, and thus hurricanes are not readily comparable to those of the Atlantic basin. Additionally some of the hurricanes passing Kauai were moving fast and this translation speed probably adds to the maximum wind. In both island areas, some minimum pressure values appear inconsistent with the given wind values. This is largely attributable to the given minimum pressure and maximum winds not necessarily being the extremes in the hurricane.

SUMMARY

In virtually every coastal city of any size from Texas to Maine, the present Tropical Prediction Center Director, Dr. Robert Burpee, or former National Hurricane Center Directors, Dr. Robert Sheets and Dr. Neil Frank, have stated that the United States is building toward a hurricane disaster. The population growth versus low hurricane experience levels indicated in Hebert, Taylor, and Case (1984), together with updated statistics presented by Jarrell, Hebert and Mayfield (1992) form the basis for their statements. Stated simply, the areas of the United States where 9 out of 10 persons have lost their lives by drowning from the storm surge during hurricanes (along the immediate Gulf of Mexico and Atlantic shorelines) are the very areas where the most dramatic increases in population have occurred in recent years. This situation, in combination with continued building on low coastal elevations, will lead to serious problems for many areas in future hurricanes. Since it is likely that people will always live along the immediate shoreline, a pleasant way of life, the solution to the problem lies in education and preparedness.

The message to coastal residents is this: Become familiar with what hurricanes can do, and when a hurricane threatens your area, increase your chances of survival by moving away from the water until the hurricane has passed! Unless this message is clearly understood by coastal residents through a thorough and continuing preparedness effort, disastrous loss of life is inevitable in the future.

Acknowledgments: The work of J.G. Taylor and R.A. Case, co-authors of previous versions of this paper, contributed much. Joan David drafted the figures. Linda Kremkau provided the 1990 census data.

NOAA SCIENTIFIC AND TECHNICAL PUBLICATIONS

NOAA, the *National Oceanic and Atmospheric Administration*, was established as part of the Department of Commerce on October 3, 1970. The mission responsibilities of NOAA are to monitor and predict the state of the solid Earth, the oceans and their living resources, the atmosphere, and the space environment of the Earth, and to assess the socioeconomic impact of natural and technological changes in the environment.

The six Major Line Components of NOAA regularly produce various types of scientific and technical information in the following kinds of publications:

PROFESSIONAL PAPERS — Important definitive research results, major techniques, and special investigations.

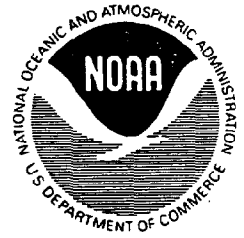
TECHNICAL REPORTS—Journal quality with extensive details, mathematical developments, or data listings.

TECHNICAL MEMORANDUMS — Reports of preliminary, partial, or negative research or technology results, interim instructions, and the like.

CONTRACT AND GRANT REPORTS—Reports prepared by contractors or grantees under NOAA sponsorship.

TECHNICAL SERVICE PUBLICATIONS—These are publications containing data, observations, instructions, etc. A partial listing: Data serials; Prediction and outlook periodicals; Technical manuals, training papers, planning reports, and information serials; and Miscellaneous technical publications.

ATLAS—Analysed data generally presented in the form of maps showing distribution of rainfall, chemical and physical conditions of oceans and atmosphere, distribution of fishes and marine mammals, ionospheric conditions, etc.



Information on availability of NOAA publications can be obtained from:
